CASE STUDY: EventHub

EventHub is a platform that allows individuals and companies to organize, promote, and manage public and private events.

When a person or a company decides to host events through the platform, they first register as an organizer by providing their name and, if applicable, the name of the company they represent.

The platform assigns each organizer a verified status after completing an internal review process. Alongside their account, every organizer maintains a public-facing profile page where they can write a short biography, link to their personal or company website, and upload a logo.

This profile page is directly tied to the organizer's account and cannot exist without it.

Once their account is set up, an organizer can publish events on the platform. Every event carries a title, a detailed description, a start date, an optional end date, and a maximum number of attendees allowed.

People who wish to attend events join the platform as attendees. Each attendee provides their full name, an email address, and a home address that includes a street, city, country, and postal code, used for correspondence purposes. The platform can issue an attendee a badge — a credential uniquely numbered per attendee, stamped with the date it was issued, and assigned a tier: either Standard or VIP.

A badge belongs to one attendee, and each attendee can have at most one badge.

Task:

Implement a full EF Core console app with all entity classes, a DbContext, and OnModelCreating fully configured.

Each entity must be configured using one technique only (Data Annotations, Fluent API, or a separate configuration class) — do not mix techniques on the same entity. Use all three techniques across the model.
